

# C / C++ / Python Programming Mastery

A standards-aligned curriculum for fundamentals, DSA, competitive programming and interviews

## The Talent Grid Candidate Revision Guide

This curriculum is designed to move candidates from basic programming to interview-grade problem solving using C, C++ and Python in a proper sequence.

**Outcome: candidates learn syntax, logic building, DSA, algorithmic thinking, debugging, mini projects and mock interview explanation.**

Learn programming in the correct sequence - from syntax to interview problem solving.

## Curriculum Roadmap

The sequence below follows how programming should be learned in a standards-aligned way: first syntax and control flow, then memory and modularity, then data structures, algorithms, projects and interviews.

### Learning Journey

| Area          | C Standard Practice         | C++ Standard Practice            | Python Standard Practice                 |
|---------------|-----------------------------|----------------------------------|------------------------------------------|
| Program entry | int main() and return 0     | int main() and fast I/O          | if __name__ == '__main__'                |
| Input         | scanf/fgets with validation | cin/cout, getline                | input(), sys.stdin for large input       |
| Memory        | Manual stack/heap awareness | RAII, references, smart pointers | Object references and garbage collection |
| Collections   | Arrays and custom structs   | STL containers                   | list, dict, set, tuple, collections      |

| Area            | C Standard Practice               | C++ Standard Practice                 | Python Standard Practice              |
|-----------------|-----------------------------------|---------------------------------------|---------------------------------------|
| Error handling  | Return codes and checks           | Exceptions plus checks                | try/except and validation             |
| Coding style    | Clear functions and headers       | STL-aware, const-correct where useful | PEP 8 inspired, readable names        |
| Interview focus | Pointers, arrays, memory, strings | STL, OOP, DSA speed                   | Clean logic, libraries, data handling |

## Complete Module Sequence

The table gives the full curriculum in the right learning order. Each module is mapped to what must be practiced in C, C++ and Python.

| Module                       | Concepts                                                                                                                 | Language Mapping                                                                                        | Candidate Outcome                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| 1. Programming Environment   | Compiler, interpreter, source code, executable, IDE, terminal, command line, CPU, memory, input and output.              | C: gcc, main(), printf, scanf  <br>C++: g++, iostream, cin, cout  <br>Python: interpreter, print, input | Candidate can compile, run and explain how a program executes.                   |
| 2. Variables and Data Types  | Declaration, initialization, integer, float, double, char, string, bool, constants, type casting and naming conventions. | C: int/float/double/char/const  <br>C++: string/bool/const   Python: int/float/str/bool/dynamic typing  | Candidate can choose the correct data type and avoid basic overflow/type errors. |
| 3. Input and Output          | Read user input, format output, handle spaces, lines, numbers and strings.                                               | C: scanf/printf   C++: cin/cout/getline   Python: input/print/f-string                                  | Candidate can write clean console programs and handle input constraints.         |
| Module                       | Concepts                                                                                                                 | Language Mapping                                                                                        | Candidate Outcome                                                                |
| 4. Operators and Expressions | Arithmetic, relational, logical, assignment, increment, decrement, bitwise operators and precedence.                     | C/C++: &&,   , !, ++, --, &,  , ^, <<, >>   Python: and/or/not, **, //                                  | Candidate can convert formulas and conditions into correct expressions.          |

| Module             | Concepts                                                                         | Language Mapping                                     | Candidate Outcome                                                                          |
|--------------------|----------------------------------------------------------------------------------|------------------------------------------------------|--------------------------------------------------------------------------------------------|
| 5. Decision Making | if, else, nested if, else-if ladder, switch-case and ternary decisions.          | C/C++: if, else, switch, ?:   Python: if, elif, else | Candidate can model business rules such as tax slab, grade, discount or eligibility logic. |
| 6. Loops           | for, while, do-while, nested loops, break, continue, infinite loops and dry run. | C/C++: for/while/do-while   Python: for range, while | Candidate can repeat logic safely and solve counting, summation and pattern problems.      |

| Module                        | Concepts                                                                                                                 | Language Mapping                                                  | Candidate Outcome                                                                  |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|------------------------------------------------------------------------------------|
| 7. Functions                  | Function declaration, definition, calling, parameters, return value, scope, local/global variables and recursion basics. | C/C++: return type and prototype   Python: def and return         | Candidate can decompose code into reusable blocks and improve readability.         |
| 8. Arrays, Lists and Matrices | Indexing, traversal, searching, insertion, deletion, 1D arrays, 2D arrays and matrices.                                  | C: fixed arrays   C++: arrays and vector   Python: list           | Candidate can solve collection-based problems and understand memory layout basics. |
| 9. Strings                    | Character arrays, string objects, traversal, length, comparison, substring, split, join, palindrome and anagram.         | C: char[], strlen, strcmp   C++: string   Python: str and slicing | Candidate can handle text input, parsing and interview string problems.            |

| Module                              | Concepts                                                                                         | Language Mapping                                                                                 | Candidate Outcome                                                                     |
|-------------------------------------|--------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| 10. Pointers, References and Memory | Address, pointer, dereference, stack, heap, dynamic memory, call by value and call by reference. | C: *, &, malloc/free   C++: references, new/delete, smart pointers   Python: object references   | Candidate understands memory-sensitive bugs, mutation and parameter passing.          |
| 11. Structures, Classes and OOP     | Struct, class, object, constructor, encapsulation, inheritance, polymorphism and abstraction.    | C: struct   C++: class, constructor, inheritance, virtual   Python: class, __init__, inheritance | Candidate can model real entities such as students, products, employees and accounts. |
| 12. File Handling                   | Open, read, write, append, close, CSV files, logs and file errors.                               | C: FILE*, fopen/fclose   C++: ifstream/ofstream   Python: with open(), csv                       | Candidate can persist data beyond program execution.                                  |

| Module                           | Concepts                                                                                                 | Language Mapping                                                                                                               | Candidate Outcome                                                                        |
|----------------------------------|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| 13. Error Handling and Debugging | Syntax error, runtime error, logical error, boundary case, defensive programming and exception handling. | C: manual checks   C++: try/catch   Python: try/except/finally                                                                 | Candidate can find defects, handle invalid input and write robust programs.              |
| 14. Standard Libraries           | Reusable library functions and containers for faster, safer implementation.                              | C: stdio, stdlib, string, math   C++: STL vector/map/set/stack/queue/algorithm   Python: collections, itertools, heapq, bisect | Candidate can avoid reinventing common operations and write interview-ready code faster. |

| Module              | Concepts                                                                          | Language Mapping                                                                | Candidate Outcome                                                       |
|---------------------|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 15. Data Structures | Array, string, stack, queue, linked list, hash table, tree, heap, graph and trie. | C: manual implementation   C++: STL plus manual   Python: built-ins plus manual | Candidate can choose the right structure for time and space efficiency. |

| Module                           | Concepts                                                                                                             | Language Mapping                                                                          | Candidate Outcome                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| 16. Algorithms                   | Searching, sorting, recursion, backtracking, two pointers, sliding window, hashing, greedy, DP and graph algorithms. | Same concepts across C, C++ and Python with language-specific implementation style.       | Candidate can solve coding interview and competitive programming problems. |
| 17. Complexity Analysis          | Big O, best case, average case, worst case, time complexity and space complexity.                                    | Language independent; used to compare brute force and optimized solutions.                | Candidate can explain why a solution passes constraints.                   |
| 18. Projects and Mock Interviews | Mini projects, timed tests, code reviews, resume explanation and final mock interviews.                              | C: records and memory projects   C++: OOP/STL projects   Python: automation/data projects | Candidate becomes ready to demonstrate skill, not just syntax knowledge.   |

## Phase 1 - Programming Foundation

This phase builds comfort with the machine, language syntax and predictable program execution.

- Understand compiler versus interpreter and how a program moves from source code to execution.
- Write first programs in C, C++ and Python using proper entry points and input/output.
- Use variables and data types correctly for numbers, text and logical values.
- Practice business-style mini problems such as marksheet, bill calculation, simple interest and temperature conversion.

**Validation: candidate can write 20 small programs without help, dry-run each line and explain expected output.**

### Foundation Flow

## Phase 2 - Logic Building

Logic building is the bridge between knowing syntax and solving real coding problems.

- Use if-else and switch-case for rule-based decisions.
- Use loops for repetition and nested loops for pattern and matrix problems.
- Break a problem into input, processing, conditions, iteration and output.
- Handle boundary cases such as zero, negative values, empty input and maximum constraints.

| Practice Area | Examples                        | What can go wrong                      | How to validate                     |
|---------------|---------------------------------|----------------------------------------|-------------------------------------|
| Conditions    | Grade, tax slab, ATM withdrawal | Wrong branch order or missed edge case | Dry-run all ranges                  |
| Loops         | Factorial, prime, Fibonacci     | Infinite loop or off-by-one            | Check first, middle and last values |
| Nested loops  | Patterns and matrices           | Wrong row/column boundary              | Trace row and column indexes        |

## Phase 3 - Functions, Recursion and Modularity

Functions make code reusable, testable and interview-ready. Recursion teaches candidates how the call stack works.

| Concept      | Meaning                              | Used for                                         | Risk if weak                        |
|--------------|--------------------------------------|--------------------------------------------------|-------------------------------------|
| Function     | A named block that performs one task | Reusable logic such as add, prime check, GCD     | Large unreadable code               |
| Parameter    | Value sent to a function             | Customizing the function input                   | Wrong result due to wrong argument  |
| Return value | Output sent back by a function       | Using function result elsewhere                  | Printing instead of returning       |
| Scope        | Where a variable is visible          | Avoiding accidental changes                      | Name conflicts and hidden bugs      |
| Recursion    | Function calling itself              | Tree traversal, backtracking, divide and conquer | Missing base case or stack overflow |

**Recommended practice: prime check, factorial, reverse number, GCD, LCM, palindrome and recursive sum of digits.**

## Phase 4 - Collections, Strings and Memory

Arrays, strings and memory concepts are essential for C/C++ interviews and still important conceptually in Python.

| Topic          | C                            | C++                          | Python                           |
|----------------|------------------------------|------------------------------|----------------------------------|
| Array/List     | Fixed-size contiguous memory | array and vector             | list object                      |
| String         | char array and string.h      | std::string                  | str with slicing and methods     |
| Matrix         | 2D array                     | vector>                      | list of lists                    |
| Pointer        | Direct address handling      | Pointer plus reference       | Object reference concept         |
| Dynamic memory | malloc/calloc/free           | new/delete and smart pointer | Garbage collector handles memory |

### Memory Thinking

## Phase 5 - Object-Oriented Programming

OOP means Object-Oriented Programming. It helps candidates model real-world entities like students, accounts, products and employees.

| OOP Concept   | Simple Meaning                  | Real Example                             | Validation                        |
|---------------|---------------------------------|------------------------------------------|-----------------------------------|
| Class         | Blueprint                       | BankAccount class                        | Can define attributes and methods |
| Object        | Actual instance                 | Savings account of one customer          | Can create multiple objects       |
| Encapsulation | Keep data and behavior together | Deposit/withdraw methods protect balance | Invalid state is prevented        |
| Inheritance   | Reuse parent behavior           | Employee -> Manager                      | Common fields not duplicated      |
| Polymorphism  | Same action, different behavior | Shape area for circle/rectangle          | Correct method selected           |
| Abstraction   | Hide internal complexity        | ATM hides banking backend                | User sees simple interface        |

## Phase 6 - Data Structures

Data structures decide how data is stored, accessed and updated. The right data structure reduces time complexity and improves code clarity.

| Sequence | Data Structure | When to use                       | Key operations             |
|----------|----------------|-----------------------------------|----------------------------|
| 1        | Array/List     | Ordered indexed data              | Access, update, traverse   |
| 2        | Stack          | Last-in-first-out problems        | Push, pop, top             |
| 3        | Queue          | First-in-first-out processing     | Enqueue, dequeue           |
| 4        | Linked List    | Frequent insert/delete with nodes | Insert, delete, reverse    |
| 5        | Hash Table     | Fast lookup by key                | Insert, find, count        |
| 6        | Tree           | Hierarchical data                 | Traversal, search          |
| 7        | Heap           | Priority-based retrieval          | Push, pop min/max          |
| 8        | Graph          | Network relationships             | BFS, DFS, shortest path    |
| 9        | Trie           | Prefix search                     | Insert word, search prefix |

## Choosing a Data Structure

## Phase 7 - Algorithms and Problem Patterns

Algorithms are reusable problem-solving patterns. Candidates should learn them as patterns, not isolated questions.

| Pattern       | What it means                                       | Typical problems                                 | Validation metric                    |
|---------------|-----------------------------------------------------|--------------------------------------------------|--------------------------------------|
| Linear Search | Check every element one by one.                     | Find item, count frequency, first match.         | $O(n)$ , correct for unsorted data.  |
| Binary Search | Repeatedly cut sorted search space in half.         | Lower bound, rotated array, answer search.       | $O(\log n)$ , no infinite loop.      |
| Sorting       | Arrange data for faster lookup or greedy decisions. | Merge intervals, rank records, count inversions. | Correct order and complexity.        |
| Two Pointers  | Use two indexes to reduce nested loops.             | Pair sum, remove duplicates, container area.     | $O(n)$ , pointer movement justified. |

| Pattern        | What it means                                        | Typical problems                               | Validation metric                                       |
|----------------|------------------------------------------------------|------------------------------------------------|---------------------------------------------------------|
| Sliding Window | Maintain a moving range over data.                   | Max sum size K, longest substring, min window. | Window invariant remains valid.                         |
| Hashing        | Use key-value lookup for fast access.                | Two sum, anagrams, subarray sum K.             | Average $O(1)$ lookup, handles collisions conceptually. |
| Recursion      | Function solves smaller version of the same problem. | Factorial, tree traversal, divide and conquer. | Base case exists, stack depth safe.                     |

| Pattern      | What it means                                | Typical problems                         | Validation metric               |
|--------------|----------------------------------------------|------------------------------------------|---------------------------------|
| Backtracking | Try choices, undo, and explore alternatives. | Subsets, permutations, N-Queens, Sudoku. | All valid states explored once. |

| Pattern             | What it means                                           | Typical problems                                | Validation metric                      |
|---------------------|---------------------------------------------------------|-------------------------------------------------|----------------------------------------|
| Greedy              | Make best local choice when it leads to global optimum. | Activity selection, meeting rooms, gas station. | Proof or counterexample reasoning.     |
| Dynamic Programming | Store answers to repeated subproblems.                  | Knapsack, LCS, LIS, edit distance.              | State, transition and base case clear. |
| Graph Algorithms    | Model relationships as nodes and edges.                 | BFS, DFS, course schedule, shortest path.       | Visited logic and edge cases correct.  |

## Competitive Programming and Interview Standards

Candidates must write fast, clean and constraint-aware code. A good answer includes approach, complexity, edge cases and final code.

### Coding Interview Answer Flow

| Skill        | Candidate should say                                 | Candidate should do                 |
|--------------|------------------------------------------------------|-------------------------------------|
| Approach     | I will first explain brute force, then optimize.     | Write steps before code.            |
| Complexity   | The solution is $O(n)$ time and $O(n)$ space.        | Connect complexity to constraints.  |
| Edge cases   | I will test empty input, one element and duplicates. | Run sample and custom tests.        |
| Code quality | I will keep logic modular and readable.              | Use functions and meaningful names. |

# Standard Code Templates

## C competitive programming starter

```
#include <stdio.h>

int main() {
    int t;
    scanf("%d", &t);

    while (t--) {
        int n;
        scanf("%d", &n);
        printf("%d\n", n);
    }

    return 0;
}
```

## C++ competitive programming starter

```
#include <bits/stdc++.h>
using namespace std;

int main() {
    ios::sync_with_stdio(false);
    cin.tie(nullptr);

    int t;
    cin >> t;
    while (t--) {
        int n;
        cin >> n;
        cout << n << '\n';
    }
    return 0;
}
```

## Python competitive programming starter

```
import sys

def solve():
    data = sys.stdin.read().split()
    index = 0
    t = int(data[index])
    index += 1

    answers = []
    for _ in range(t):
        n = int(data[index])
        index += 1
        answers.append(str(n))

    print("\n".join(answers))

if __name__ == "__main__":
    solve()
```

## 90-Day Training Plan

This schedule can be used as a The Talent Grid programming track for college students, freshers and candidates preparing for service-based and product-based coding rounds.

| Week | Focus                                                               | C/C++/Python Output                                    |
|------|---------------------------------------------------------------------|--------------------------------------------------------|
| 1    | Programming setup, compiler/interpreter, variables, data types, I/O | 10 console programs in each selected language          |
| 2    | Operators, conditions, loops and pattern printing                   | Number logic and nested loop problem set               |
| 3    | Functions, scope, recursion basics                                  | Reusable function library for common math/string tasks |
| 4    | Arrays, lists, strings and basic sorting/searching                  | Array/string interview starter problems                |

| Week | Focus                                                  | C/C++/Python Output                         |
|------|--------------------------------------------------------|---------------------------------------------|
| 5    | Pointers, references, memory model, structures/classes | Memory exercises and OOP mini examples      |
| 6    | Stack, queue, linked list and hashing                  | Manual and library-based implementations    |
| 7    | Binary search, two pointers, sliding window, recursion | Pattern-wise coding drill                   |
| 8    | Trees, heaps, graphs, BFS and DFS                      | Traversal and graph representation problems |

| Week | Focus                                        | C/C++/Python Output                              |
|------|----------------------------------------------|--------------------------------------------------|
| 9    | Greedy, bit manipulation and DP foundations  | Classic optimization problems                    |
| 10   | Advanced DP and graph algorithms             | Shortest path, topological sort, LCS, knapsack   |
| 11   | Timed coding tests and optimization          | Mixed problem sets with complexity explanation   |
| 12   | Projects, mock interviews and final revision | Final project demo and interview readiness score |

## Project-Based Learning

Projects prove that the candidate can apply programming concepts beyond isolated problems. Each project should be version-controlled, explained and tested.

| Language | Beginner Projects                      | Intermediate Projects                          | Advanced Projects                                 |
|----------|----------------------------------------|------------------------------------------------|---------------------------------------------------|
| C        | Calculator, marksheet, number guessing | Banking with structures, file employee records | Linked-list contact book, inventory with files    |
| C++      | Student class, shopping cart           | Library system, STL inventory, parking lot     | LRU cache, graph route finder, CP toolkit         |
| Python   | Calculator, to-do app, word counter    | CSV analytics, expense tracker, JSON processor | Resume analyzer, automation scripts, API mini app |

**Project validation checklist: working demo, readable code, file or data handling where relevant, error handling, test cases and a clear resume explanation.**

## Candidate Assessment Rubric

Use this rubric to score candidate readiness before interviews or placement drives.

| Assessment Area         | Weight | What to check                                                                |
|-------------------------|--------|------------------------------------------------------------------------------|
| Syntax and fundamentals | 15%    | Can write correct basic programs without copying.                            |
| Logic building          | 20%    | Can dry-run, handle conditions and loops, and solve small problems.          |
| Data structures         | 20%    | Can choose and implement arrays, stack, queue, hash map, tree and graph.     |
| Algorithms              | 20%    | Can explain and code search, sort, recursion, DP, greedy and graph patterns. |
| Debugging               | 10%    | Can find boundary cases, invalid input, off-by-one and memory issues.        |
| Code readability        | 5%     | Uses names, functions, comments and clean formatting.                        |
| Project implementation  | 10%    | Can build and explain working mini projects.                                 |

### Final readiness levels:

- Below 50: needs foundation rebuild and daily coding discipline.
- 50 to 70: has basics but needs structured DSA and timed practice.
- 70 to 85: interview-ready for many service-based roles with mock practice.

- 85 plus: strong candidate for tougher coding rounds and advanced interviews.

## Final Revision Checklist

| Checklist Item          | Ready when candidate can...                                                  |
|-------------------------|------------------------------------------------------------------------------|
| Syntax                  | Write basic programs in C/C++/Python without copying.                        |
| Dry run                 | Trace variables, loops and recursion on paper.                               |
| Debugging               | Find off-by-one, invalid input and memory-related errors.                    |
| DSA                     | Choose array, hash map, stack, queue, tree or graph based on the problem.    |
| Algorithms              | Explain brute force, optimized approach, complexity and edge cases.          |
| Projects                | Demo at least one project per language track or one strong combined project. |
| Interview communication | Explain approach before coding and test after coding.                        |

**Positioning: C/C++/Python Programming Mastery for Coding Interviews - from programming fundamentals to DSA, projects and mock interviews.**
